Abstract. We present new sound and complete axiomatizations of type equality and sub-type inequality for a first-order type language with regular recursive types. The rules are motivated by coinductive characterizations of type containment and type equality via simulation and bisimulation, respectively. The main novelty of the axiomatization is the *fixpoint rule* (or *coinduction principle*). It states that from $A, P \vdash P$ one may deduce $A \vdash P$, where P is either a type equality $\tau = \tau'$ or type containment $\tau \leq \tau'$ and the proof of the premise must be *contractive* in a sense we define in this paper. In particular, a proof of $A, P \vdash P$ using the assumption axiom is *not* contractive. The fixpoint rule embodies a finitary coinduction principle and thus allows us to capture a coinductive relation in the fundamentally inductive framework of inference systems.

The new axiomatizations are more concise than previous axiomatizations, particularly so for type containment since no separate axiomatization of type equality is required, as in Amadio and Cardelli's axiomatization. They give rise to a natural operational interpretation of proofs as *coercions*. In particular, the fixpoint rule corresponds to *definition by recursion*. Finally, the axiomatization is closely related to (known) efficient algorithms for deciding type equality and type containment. These can be modified to not only *decide* type equality

*This work was partially supported by Danish Research Council Project DART. The results were obtained and written up at DIKU, University of Copenhagen.

and type containment, but also construct proofs in our axiomatizations efficiently. In connection with the operational interpretation of proofs as coercions this gives *efficient* ($O(n^2)$ time) algorithms for constructing *efficient* coercions from a type to any of its supertypes or isomorphic types.

More generally, we show how adding the fixpoint rule makes it possible to characterize *inductively* a set that is *coinductively* defined as the kernel (greatest fixed point) of an inference system.

Keywords: subtyping, type equality, recursive type, coercion, coinduction, operational interpretation, axiomatization, inference system, inference rule, fixpoint

1. Introduction

The simply typed λ -calculus is paradigmatic for both type inference for programming languages and the Curry-Howard isomorphism. Its typing rules are given by

$$A, x : \tau, B \vdash x : \tau \quad \text{if } x \notin B$$

$$\frac{A, x : \tau \vdash e : \tau'}{A \vdash \lambda x : \tau. e : \tau \rightarrow \tau'}$$

$$\frac{A \vdash e : \tau \rightarrow \tau' \quad A \vdash e' : \tau}{A \vdash ee' : \tau'}$$

Whereas adding recursive types destroys its strong normalization property and its logical soundness under the Curry-Howard interpretation, recursive types preserve and extend the “well-typed programs don’t go wrong” property of λ -terms. To use recursive types it is necessary to add the rule

$$\frac{A \vdash e : \tau \quad \vdash \tau = \tau'}{A \vdash e : \tau'} \quad (\text{EQUAL})$$

for simple typing with recursive types [CC91] or

$$\frac{A \vdash e : \tau \quad \vdash \tau \leq \tau'}{A \vdash e : \tau'} \quad (\text{SUBTYPE})$$

for simple subtyping with recursive types [AC91, AC93]. The question, now, is when two recursive types are equal or in the subtyping relation. This is what we study in this paper.

1.1. Recursive Types

Definition 1.1. The *recursive types (in canonical form)* μTp are generated by the grammar

$$\tau \equiv \perp \mid \top \mid \alpha \mid \tau_1 \rightarrow \tau_2 \mid \mu\alpha.(\tau_1 \rightarrow \tau_2)$$

where α ranges over an infinite set TVar of *type variables*, μ binds its type variable, recursive types that differ only in their bound variables are identified, and in every $\mu\alpha.\tau$ the bound variable α occurs freely in τ .

Intuitively, $\mu\alpha.\tau$ denotes the recursive type defined by the type equation $\alpha = \tau$ (note that α occurs in τ), \perp is contained in all other types, and \top contains all other types. We let τ, σ range over recursive types and write $\text{fv}(\tau)$ for the set of free type variables in τ .

Our results extend to other types and type constructors such as product and sum, but for clarity we shall not treat these extensions here.

1.2. Regular Trees

We define $\text{Tree}(\tau)$ to be the regular (possibly infinite) tree obtained by completely unfolding all occurrences of $\mu\alpha.\tau$ to $\tau[\mu\alpha.\tau]$. (For a precise definition of $\text{Tree}(\tau)$, regular trees and their properties see [Cou83, CC91, AC93].) We write $T_1 \rightarrow T_2$ for the tree T with root label \rightarrow , left subtree T_1 and right subtree T_2 .

Henceforth we shall assume that all trees are over the ranked alphabet $\{\perp^0, \rightarrow^2, \top^0\} \cup \{\alpha^0 : \alpha \in \text{TVar}\}$ of *labels*, which are ordered by the reflexive-transitive closure of $\perp < \xrightarrow{\alpha} < \top$.

We can define *depth- k lower and upper approximations* $T|_k$ and $T|_k^k$ of a tree T as follows:

$$\begin{array}{ll} T|_0 = \perp & T|_0^k = \top \\ (T' \rightarrow T'')|_{k+1} = T'|_k \rightarrow T''|_k & (T' \rightarrow T'')|_{k+1}^k = T'|_k \rightarrow T''|_k^k \\ \perp|_{k+1} = \perp & \perp|_{k+1}^k = \perp \\ \top|_{k+1} = \top & \top|_{k+1}^k = \top \\ \alpha|_{k+1} = \alpha & \alpha|_{k+1}^k = \alpha \end{array}$$

For tree T , $\mathcal{L}(T)$, the *label* of T , is the label of the root node of T :

$$\begin{aligned} \mathcal{L}(\perp) &= \perp \\ \mathcal{L}(T \rightarrow T') &= \rightarrow \\ \mathcal{L}(\top) &= \top \\ \mathcal{L}(\alpha) &= \alpha \end{aligned}$$

The label of a recursive type τ is the label of the tree it denotes: $\mathcal{L}(\tau) = \mathcal{L}(\text{Tree}(\tau))$.

$$\begin{array}{c}
\vdash \tau = \tau \qquad \frac{\vdash \tau = \tau' \quad \vdash \tau' = \tau''}{\vdash \tau = \tau''} \qquad \frac{\vdash \tau' = \tau}{\vdash \tau = \tau'} \\
\\
\frac{\vdash \tau = \tau' \quad \vdash \sigma = \sigma'}{\vdash \tau \rightarrow \sigma = \tau' \rightarrow \sigma'} \qquad \frac{\vdash \tau = \tau'}{\vdash \mu\alpha.\tau = \mu\alpha.\tau'} \quad (\mu\text{-COMPAT}) \\
\\
\vdash \mu\alpha.\tau = \tau[\mu\alpha.\tau/\alpha] \qquad (\text{FOLD/UNFOLD}) \\
\\
\frac{\vdash \tau_1 = \tau[\tau_1/\alpha] \quad \vdash \tau_2 = \tau[\tau_2/\alpha]}{\vdash \tau_1 = \tau_2} \quad (\tau \text{ contractive in } \alpha) \quad (\text{CONTRACT})
\end{array}$$

Figure 1. Classical axiomatization of recursive type equality

1.3. Recursive Type Equality

Cardone and Coppo [CC91] show the following results about recursive type equality (for types without \top):

- Interpreting recursive types as ideals in a universal domain, τ, τ' are *semantically equivalent* (denote the same ideal) if and only if $\text{Tree}(\tau) = \text{Tree}(\tau')$.
- *Weak type equality*, the congruence generated by axiom FOLD/UNFOLD in Figure 1, is properly weaker than semantic type equivalence.
- The principal typing property in the sense of Hindley [Hin69] and Ben-Yelles [BY79] extends to simple typing with recursive types if type equality in Rule (EQUAL) is taken to be semantic type equivalence, yet it breaks if it is defined as weak equality.

Let us write $\tau \approx \tau'$ if $\text{Tree}(\tau) = \text{Tree}(\tau')$. Axiomatizations of \approx are given by Amadio/Cardelli [AC91] and Ariola/Klop [AK95]. It is clear, however, that this kind of axiomatization has been known for a long time; see for example Salomaa [Sal66], Milner [Mil84] and Kozen [Koz94].

All these axiomatizations are a variant of the inference system presented in Figure 1.¹ (In Rule CONTRACT, recursive type τ is contractive in type variable α if α occurs in τ only under \rightarrow , if at all.)

¹Instead of Rule CONTRACT Ariola and Klop [AK95] use the equivalent rule

$$\frac{\vdash \tau_1 = \tau[\tau_1/\alpha]}{\mu\alpha.\tau = \tau_1} \quad \tau \text{ contractive in } \alpha.$$

$$\begin{array}{c}
\Gamma \vdash \perp \leq \tau \qquad \qquad \qquad \Gamma \vdash \tau \leq \top \\
\\
\Gamma \vdash \tau \leq \tau \qquad \qquad \qquad \frac{\Gamma \vdash \tau \leq \tau' \quad \Gamma \vdash \tau' \leq \tau''}{\Gamma \vdash \tau \leq \tau''} \\
\\
\Gamma, \tau \leq \tau', \Gamma' \vdash \tau \leq \tau' \qquad \qquad \frac{\Gamma \vdash \tau = \tau'}{\Gamma \vdash \tau \leq \tau'} \\
\\
\frac{\Gamma \vdash \tau' \leq \tau \quad \Gamma \vdash \sigma \leq \sigma'}{\Gamma \vdash \tau \rightarrow \sigma \leq \tau' \rightarrow \sigma'} \qquad \frac{\Gamma, \alpha \leq \beta \vdash \tau \leq \sigma}{\Gamma \vdash \mu\alpha.\tau \leq \mu\beta.\sigma} \quad (\alpha, \beta \text{ not free in } \sigma, \tau)
\end{array}$$

Figure 2. Amadio/Cardelli axiomatization of subtyping for recursive types

1.4. Recursive Subtyping

Amadio and Cardelli [AC93] extend the standard contravariant structural subtyping relation on μ -free types (to be thought of as finite trees) defined by

$$\begin{array}{c}
\perp \leq_{\text{fin}} T \quad (\perp_{\text{fin}}) \qquad \qquad T \leq_{\text{fin}} \top \quad (\top_{\text{fin}}) \\
\\
T \leq_{\text{fin}} T \quad (\text{REF}_{\text{fin}}) \qquad \qquad \frac{S_1 \leq_{\text{fin}} T_1 \quad T_2 \leq_{\text{fin}} S_2}{T_1 \rightarrow T_2 \leq_{\text{fin}} S_1 \rightarrow S_2} \quad (\text{ARROW}_{\text{fin}})
\end{array}$$

in a natural fashion to infinite trees.

Definition 1.2. (Amadio/Cardelli subtype relation) Let τ, σ be recursive types. Define $\tau \leq_{\text{AC}} \sigma$ if $\text{Tree}(\tau)|_k \leq_{\text{fin}} \text{Tree}(\sigma)|_k$ for all $k \in \mathbb{N}_0$.

In the definition we could replace the lower approximations by upper approximations since both induce the same subtyping relation:

Proposition 1.1. $T|_k \leq_{\text{fin}} T'|_k$ if and only if $T|_k \leq_{\text{fin}} T'|_k$.

Alternatively, we could simply define depth- k approximations by mapping every node in a tree at level k to \perp (or \top for that matter). In either case the same subtype relation is defined.

Amadio and Cardelli build on the axiomatization of type equality in Figure 1 and give a sound and complete axiomatization of \leq_{AC} in [AC93], shown in Figure 2.

1.5. The New Axiomatizations

In this paper we show that the Amadio/Cardelli subtype relation can be directly axiomatized by the inference system in Figure 3.

$$\begin{array}{c}
A \vdash \perp \leq \tau \quad (\perp) \qquad A \vdash \tau \leq \top \quad (\top) \\
\\
A \vdash \tau \leq \tau \quad (\text{REF}) \qquad \frac{A \vdash \tau \leq \delta \quad A \vdash \delta \leq \sigma}{A \vdash \tau \leq \sigma} \quad (\text{TRANS}) \\
\\
A \vdash \mu\alpha.\tau \leq \tau[\mu\alpha.\tau/\alpha] \quad (\text{UNFOLD}) \qquad A \vdash \tau[\mu\alpha.\tau/\alpha] \leq \mu\alpha.\tau \quad (\text{FOLD}) \\
\\
A, \tau \leq \sigma, A' \vdash \tau \leq \sigma \quad (\text{HYP}) \\
\\
\frac{A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2 \vdash \sigma_1 \leq \tau_1 \quad A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2 \vdash \tau_2 \leq \sigma_2}{A \vdash \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2} \quad (\text{ARROW/FIX})
\end{array}$$

Figure 3. Coinductive axiomatization of Amadio/Cardelli subtyping

The most noteworthy aspect of the system is rule ARROW/FIX for proving inequality between function types. It can be understood as the composition of the two separate rules

$$\frac{A \vdash \sigma_1 \leq \tau_1 \quad A \vdash \tau_2 \leq \sigma_2}{A \vdash \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2} \quad (\text{ARROW}) \qquad \frac{A, \tau \leq \tau' \vdash \tau \leq \tau'}{A \vdash \tau \leq \tau'} \quad (\text{FIX})$$

where the premise of obviously “dangerous” Rule FIX must be proved by Rule ARROW. Rule FIX says that we may actually use as a hypothesis what we want to prove when trying to prove it. We are just not allowed to use it “right away”!

The system is *sound and complete* for Amadio/Cardelli subtyping: $\vdash \tau \leq \tau'$ if and only if $\tau \leq_{\text{AC}} \tau'$. Because of Rule ARROW/FIX, more specifically the part corresponding to Rule FIX, soundness is actually a tricky issue. The proof is accomplished by giving sequents a level-stratified interpretation. Completeness is shown by exhibiting an algorithm that builds a derivation for given (τ, τ') and succeeds whenever $\tau \leq_{\text{AC}} \tau'$. The crucial part here is showing that the algorithm terminates. The algorithm not only *decides* whether $\vdash \tau \leq \tau'$, but also returns an explicit proof. (It is relatively easy to see that the algorithm can be implemented in time $O(n^2)$ where n is the number of symbols in the two input types, but this is not elaborated in this paper. See [Car93, KPS95] for efficient algorithms for deciding recursive subtyping.)

Given our “innate” axiomatization of \leq_{AC} by \leq in Figure 3 the semantic type equivalence \approx can now be *defined* in terms of subtyping since $\tau \approx \tau'$ if and only if $\tau \leq_{\text{AC}} \tau'$ and $\tau' \leq_{\text{AC}} \tau$ if and only if $\vdash \tau \leq \tau'$ and $\vdash \tau' \leq \tau$. Alternatively, we can provide a direct axiomatization of \approx , see Figure 4. Note that it requires neither Rule CONTRACT nor Rule μ -COMPAT, which are difficult to interpret denotationally and operationally.

$$\begin{array}{c}
A, \tau = \tau', A' \vdash \tau = \tau' \quad A \vdash \tau = \tau \\
\\
\frac{A \vdash \tau = \tau'}{A \vdash \tau' = \tau} \quad \frac{A \vdash \tau = \tau' \quad A \vdash \tau' = \tau''}{A \vdash \tau = \tau''} \\
\\
A \vdash \mu\alpha. \tau = \tau[\mu\alpha. \tau / \alpha] \\
\\
\frac{A, \tau \rightarrow \tau' = \sigma \rightarrow \sigma' \vdash \tau = \sigma \quad A, \tau \rightarrow \tau' = \sigma \rightarrow \sigma' \vdash \tau' = \sigma'}{A \vdash \tau \rightarrow \tau' = \sigma \rightarrow \sigma'}
\end{array}$$

Figure 4. Coinductive axiomatization of recursive type equality

1.6. Overview of the paper

The above results for subtyping are presented in Section 2. The corresponding results for type equality are analogous; they are omitted for space reasons.

Our coinductive axiomatizations do not only support direct coinductive reasoning, but also provide a natural foundation for a proof theory and operational interpretation of proofs. In Section 3 we briefly introduce the term language of *coercions* for proofs in our subtyping axiomatization. Each rule corresponds to a natural construction on coercions; in particular, the fixpoint rule corresponds to definition by recursion.

In Section 4 we discuss why and in which precise sense our axiomatization is coinductive. In this process we give a general recipe for axiomatizing finitarily coinductive relations. Finally, Section 5 describes the present, related and future work.

2. Recursive Types: Subtyping

2.1. Simulations on Recursive Types

We give a characterization of \leq_{AC} that highlights the coinductive nature of \leq_{AC} . Its advantages are that it is intrinsically in terms of recursive types, without referring to infinite trees, and it directly reflects the characteristic closure properties of \leq_{AC} . It will be used in the proof of completeness for our axiomatization of \leq_{AC} .

Definition 2.1. (Simulation on recursive types) A *simulation (on recursive types)* is a binary relation \mathcal{R} on recursive types satisfying:

- (i) $(\tau_1 \rightarrow \tau_2) \mathcal{R} (\sigma_1 \rightarrow \sigma_2) \Rightarrow \sigma_1 \mathcal{R} \tau_1$ and $\tau_2 \mathcal{R} \sigma_2$

- (ii) $\mu\alpha.\tau \mathcal{R} \sigma \Rightarrow \tau[\mu\alpha.\tau/\alpha] \mathcal{R} \sigma$
- (iii) $\tau \mathcal{R} \mu\beta.\sigma \Rightarrow \tau \mathcal{R} \sigma[\mu\beta.\sigma/\beta]$
- (iv) $\tau \mathcal{R} \sigma \Rightarrow \mathcal{L}(\tau) \leq \mathcal{L}(\sigma)$

Lemma 2.1. \leq_{AC} is a simulation.

Proof:

We prove the four properties of Definition 2.1.

(i) Assume $\tau_1 \rightarrow \tau_2 \leq_{\text{AC}} \sigma_1 \rightarrow \sigma_2$ and let $k \in \mathbb{N}_0$. By Definition 1.2 we have

$$\text{Tree}(\tau_1 \rightarrow \tau_2) \upharpoonright_{(k+1)} \leq_{\text{fin}} \text{Tree}(\sigma_1 \rightarrow \sigma_2) \upharpoonright_{(k+1)}.$$

By definition of $\text{Tree}(\cdot)$ and of the k 'th lower approximation we find

$$\left(\text{Tree}(\tau_1) \upharpoonright_k \rightarrow \text{Tree}(\tau_2) \upharpoonright_k \right) \leq_{\text{fin}} \left(\text{Tree}(\sigma_1) \upharpoonright_k \rightarrow \text{Tree}(\sigma_2) \upharpoonright_k \right)$$

and thus $\text{Tree}(\sigma_1) \upharpoonright_k \leq_{\text{fin}} \text{Tree}(\tau_1) \upharpoonright_k$ and $\text{Tree}(\tau_2) \upharpoonright_k \leq_{\text{fin}} \text{Tree}(\sigma_2) \upharpoonright_k$. Since k was chosen to be arbitrary and $\text{Tree}(\sigma_1) \upharpoonright_k \leq_{\text{fin}} \text{Tree}(\tau_1) \upharpoonright_k$ if and only if $\text{Tree}(\sigma_1) \upharpoonright_k \leq_{\text{fin}} \text{Tree}(\tau_1) \upharpoonright_k$ (Proposition 1.1) we finally obtain $\sigma_1 \leq_{\text{AC}} \tau_1$ and $\tau_2 \leq_{\text{AC}} \sigma_2$ as desired.

(ii) Consider $\mu\alpha.\tau \leq_{\text{AC}} \sigma$. By definition of $\text{Tree}(\cdot)$ we have $\text{Tree}(\mu\alpha.\tau) = \text{Tree}(\tau[\mu\alpha.\tau/\alpha])$ and thereby $\tau[\mu\alpha.\tau/\alpha] \leq_{\text{AC}} \sigma$.

(iii) Exactly as (ii).

(iv) Let $\tau \leq_{\text{AC}} \sigma$ and thus $\text{Tree}(\tau) \upharpoonright_k \leq_{\text{fin}} \text{Tree}(\sigma) \upharpoonright_k$ for all $k \in \mathbb{N}_0$. By inspection of \leq_{fin} we get $\mathcal{L}(\text{Tree}(\tau) \upharpoonright_k) \leq \mathcal{L}(\text{Tree}(\sigma) \upharpoonright_k)$. For $k > 0$ we obviously have $\mathcal{L}(\text{Tree}(\tau) \upharpoonright_k) = \mathcal{L}(\text{Tree}(\tau)) = \mathcal{L}(\tau)$ and hence $\mathcal{L}(\tau) \leq \mathcal{L}(\sigma)$.

□

Lemma 2.2. If \mathcal{R} is a simulation then $\tau \mathcal{R} \sigma \Rightarrow \tau \leq_{\text{AC}} \sigma$ for all $\tau, \sigma \in \mu \text{Tp}$.

Proof:

We prove $\forall k \in \mathbb{N}_0. \forall \tau, \sigma \in \mu \text{Tp}. (\tau \mathcal{R} \sigma \Rightarrow \text{Tree}(\tau) \upharpoonright_k \leq_{\text{fin}} \text{Tree}(\sigma) \upharpoonright_k)$ by induction on k .

Case $k = 0$: Trivial, since $\perp \leq_{\text{fin}} \perp$.

Case $k > 0$: Let τ, σ be given such that $\tau \mathcal{R} \sigma$. We perform a case analysis on the syntactic forms of τ, σ where $\mathcal{L}(\tau) \leq \mathcal{L}(\sigma)$. The only possible combinations of τ and σ are

τ	σ
\perp	σ
τ	\top
α	α
$\tau_1 \rightarrow \tau_2$	$\sigma_1 \rightarrow \sigma_2$
$\mu\alpha.\tau'$	$\sigma_1 \rightarrow \sigma_2$
$\tau_1 \rightarrow \tau_2$	$\mu\beta.\sigma'$
$\mu\alpha.\tau'$	$\mu\beta.\sigma'$

Case $\tau = \perp$ or $\sigma = \top$ or $\tau = \alpha$, $\sigma = \alpha$: Trivial.

Case $\tau = \mu\alpha.\tau'$, $\sigma = \sigma_1 \rightarrow \sigma_2$: τ is canonical so $\tau'[\tau/\alpha] = \tau_1 \rightarrow \tau_2$ for some τ_1, τ_2 . By Definition 2.1 (ii) we have $(\tau_1 \rightarrow \tau_2)\mathcal{R}(\sigma_1 \rightarrow \sigma_2)$ and thus by (i) $\sigma_1\mathcal{R}\tau_1$, $\tau_2\mathcal{R}\sigma_2$. Our induction hypothesis yields

$$\text{Tree}(\sigma_1)|_{(k-1)} \leq_{\text{fin}} \text{Tree}(\tau_1)|_{(k-1)} \text{ and } \text{Tree}(\tau_2)|_{(k-1)} \leq_{\text{fin}} \text{Tree}(\sigma_2)|_{(k-1)}.$$

By Proposition 1.1 and Rule $\text{ARROW}_{\text{fin}}$ we conclude

$$\text{Tree}(\tau_1)|_{(k-1)} \rightarrow \text{Tree}(\tau_2)|_{(k-1)} \leq_{\text{fin}} \text{Tree}(\sigma_1)|_{(k-1)} \rightarrow \text{Tree}(\sigma_2)|_{(k-1)}$$

which by definition of $\text{Tree}(\cdot)$ and $|_k$ implies

$$\text{Tree}(\tau) = \text{Tree}(\tau_1 \rightarrow \tau_2)|_k \leq_{\text{fin}} \text{Tree}(\sigma_1 \rightarrow \sigma_2)|_k = \text{Tree}(\sigma).$$

The remaining cases follow the same schema as the previous one, since they all have \rightarrow labels. \square

Theorem 2.1. (Characterization of Amadio/Cardelli subtyping)

$\tau \leq_{\text{AC}} \sigma$ if and only if there exists a simulation \mathcal{R} such that $\tau\mathcal{R}\sigma$.

Proof:

Follows by Lemma 2.1 and Lemma 2.2. \square

2.2. Soundness

We might want to interpret a sequent $\sigma_{11} \leq \sigma_{12}, \dots, \sigma_{n1} \leq \sigma_{n2} \vdash \tau \leq \tau'$ conventionally as “if $\sigma_{11} \leq_{\text{AC}} \sigma_{12}, \dots, \sigma_{n1} \leq_{\text{AC}} \sigma_{n2}$ then $\tau \leq_{\text{AC}} \tau'$ ” and prove every inference rule sound under this interpretation.

The problem is that Rule ARROW/FIX — more specifically the part that corresponds to Rule FIX — is *unsound* under this interpretation! To see this, consider for example $(\perp \rightarrow \top) \leq (\top \rightarrow \perp) \vdash \top \leq \perp$. Since $\perp \rightarrow \top \not\leq_{\text{AC}} \top \rightarrow \perp$ it is vacuously valid under the conventional interpretation. Application of Rule ARROW/FIX lets us deduce $\vdash \perp \rightarrow \top \leq \top \rightarrow \perp$, which is, however, *not* valid.

This does not mean that our inference system is unsound. The problem is that the interpretation of sequents is *too strong* (in the sense of “too many sequents are valid”): the premise $(\perp \rightarrow \top) \leq (\top \rightarrow \perp) \vdash \top \leq \perp$, which is obviously not derivable anyway, should not be valid. As suggested by Martín Abadi [Aba96] we give sequents a *level-stratified* interpretation, under which all inference rules are sound.

Definition 2.2. (Stratified sequent interpretation) Let k range over the nonnegative integers. Define:

1. $\models_k \tau \leq \tau'$ if $\text{Tree}(\tau)|_k \leq \text{Tree}(\tau')|_k$.

2. $\models_k A$ if $\models_k \tau \leq \tau'$ for all $\tau \leq \tau' \in A$.
3. $A \models_k \tau \leq \tau'$ if $\models_k A$ implies $\models_k \tau \leq \tau'$.
4. $A \models \tau \leq \tau'$ if $A \models_k \tau \leq \tau'$ for all $k \in \mathbb{N}_0$.

We write $\models \tau \leq \tau'$ instead of $A \models \tau \leq \tau'$ if A is empty.

Note that $\perp \rightarrow \top \leq \top \rightarrow \perp \vdash \top \leq \perp$ does *not* hold under this interpretation; that is, $(\perp \rightarrow \top) \leq (\top \rightarrow \perp) \not\models \top \leq \perp$. To wit, we have $(\perp \rightarrow \top) \leq (\top \rightarrow \perp) \models_0 \top \leq \perp$ and $(\perp \rightarrow \top) \leq (\top \rightarrow \perp) \models_k \top \leq \perp$ for all $k \geq 2$, but $(\perp \rightarrow \top) \leq (\top \rightarrow \perp) \not\models_1 \top \leq \perp$ since $\text{Tree}(\perp \rightarrow \top)|_1 = \top \rightarrow \perp = \text{Tree}(\top \rightarrow \perp)|_1$, yet $\text{Tree}(\top)|_1 = \top \not\leq \perp = \text{Tree}(\perp)|_1$. Intuitively, a sequent $A \vdash \tau \leq \tau'$ that holds vacuously (because the assumptions are false) under the conventional interpretation holds under the stratified interpretation only if $\tau \leq \tau'$ is not wrong “earlier” than an assumption in A when descending into the trees in A and $\tau \leq \tau'$ in lockstep.

Lemma 2.3. (Soundness of inference rules) *If $A \vdash \tau \leq \tau'$ then $A \models \tau \leq \tau'$.*

Proof:

The proof is by rule induction on the rules in Figure 3. For all rules but ARROW/FIX it is easy to prove $A \models_k \tau \leq \tau'$ for arbitrary k and then generalize over k . For Rule ARROW/FIX we require induction on k .

Recall Rule ARROW/FIX:

$$\frac{A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2 \vdash \sigma_1 \leq \tau_1 \quad A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2 \vdash \tau_2 \leq \sigma_2}{A \vdash \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2}$$

Our major induction hypothesis IH1 is

$$A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2 \models \sigma_1 \leq \tau_1 \text{ and } A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2 \models \tau_2 \leq \sigma_2.$$

We now prove $\forall k \in \mathbb{N}_0. A \models_k \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$ by induction on k .

Base case: $k = 0$. Trivial since $\text{Tree}(\tau)|_0 = \perp$ for all τ .

Inductive case: $k > 0$. Assume $A \models_{(k-1)} \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$ (minor induction hypothesis IH2). We need to show $A \models_k \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$; that is,

$$\models_k A \text{ implies } \models_k \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2.$$

Assume $\models_k A$. This implies that $\models_{(k-1)} A$. Since $A \models_{(k-1)} \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$ by IH2 we obtain $\models_{(k-1)} \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$ and thus $\models_{(k-1)} A, \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$. Invoking IH1 we derive $\models_{(k-1)} \sigma_1 \leq \tau_1$ and $\models_{(k-1)} \tau_2 \leq \sigma_2$, which together are equivalent to $\models_k \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$, and we are done.

□

Theorem 2.2. (Soundness for Amadio/Cardelli subtyping)

If $\vdash \tau \leq \tau'$ then $\tau \leq_{AC} \tau'$.

Proof:

Follows immediately from Lemma 2.3 and the observation that $\models \tau \leq \tau'$ if and only if $\tau \leq_{AC} \tau'$.

□

2.3. Completeness

This section is concerned with the completeness of the inference system in Figure 3 with respect to \leq_{AC} . The proof is divided into three parts; 1) an algorithm **S** that produces derivations, 2) a termination proof and finally 3) a correctness proof for **S**.

2.3.1. Algorithm S

Consider Algorithm **S** in Figure 5. The first clause in **S** that matches a particular argument tuple is executed. The only cases requiring remarks are those concerning function types. A pair of function types may have been encountered earlier in the computation and is therefore stored in the assumption set. If that is the case, rule HYP is applied and otherwise rule ARROW/FIX. It is of vital importance that assumptions are checked before applying the ARROW/FIX rule, since otherwise we would never be able to use them.

<pre> 1: S($A, \mu\alpha.\tau, \sigma$) = 2: let 3: $\mathcal{D}_1 = \text{UNFOLD}$ 4: $\mathcal{D}_2 = \mathbf{S}(A, \tau[\mu\alpha.\tau/\alpha], \sigma)$ 5: in 6: $\text{TRANS}(\mathcal{D}_1, \mathcal{D}_2)$ 7: end 8: S($A, \tau, \mu\beta.\sigma$) = 9: let 10: $\mathcal{D}_1 = \mathbf{S}(A, \tau, \sigma[\mu\beta.\sigma/\beta])$ 11: $\mathcal{D}_2 = \text{FOLD}$ 12: in 13: $\text{TRANS}(\mathcal{D}_1, \mathcal{D}_2)$ 14: end </pre>	<pre> 15: S($(A, \tau \leq \sigma, A'), \tau, \sigma$) = HYP 16: S($A, \tau_1 \rightarrow \tau_2, \sigma_1 \rightarrow \sigma_2$) = 17: let 18: $A' = A \cup \{\tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2\}$ 19: $\mathcal{D}_1 = \mathbf{S}(A', \sigma_1, \tau_1)$ 20: $\mathcal{D}_2 = \mathbf{S}(A', \tau_2, \sigma_2)$ 21: in 22: $\text{ARROW/FIX}(\mathcal{D}_1, \mathcal{D}_2)$ 23: end 24: S(A, α, α) = REF 25: S(A, \perp, τ) = \perp 26: S(A, τ, \top) = \top 27: S(A, τ, σ) = exception </pre>

2.3.2. Termination of S

Syntactic subterms We first introduce the concept of subterm closure. It corresponds to Kozen's closure operator for $L\mu$ -formulas [Koz82, p. 352], which, in turn, is motivated by the Fischer-Ladner closure for propositional dynamic logic [FL77]. Every recursive type has only a finite number of syntactic subterms, even though recursive types may have syntactic subterms that are larger than themselves; indeed, the number of syntactic subterms of a recursive type

is bounded by its size. For completeness we prove this fact here. We require a number of preliminary technical results.

Definition 2.3. A recursive type τ' is a *syntactic subterm* (or just *subterm*) of τ if $\tau' \sqsubseteq \tau$, where \sqsubseteq is defined by the following rules:

$$\begin{array}{c} \tau \sqsubseteq \tau \quad (\text{REF}) \qquad \frac{\tau \sqsubseteq \sigma[\mu\alpha.\sigma/\alpha]}{\tau \sqsubseteq \mu\alpha.\sigma} \quad (\text{UNFOLD}) \\[10pt] \frac{\tau \sqsubseteq \sigma_1}{\tau \sqsubseteq \sigma_1 \rightarrow \sigma_2} \quad (\text{ARROW}_L) \qquad \frac{\tau \sqsubseteq \sigma_2}{\tau \sqsubseteq \sigma_1 \rightarrow \sigma_2} \quad (\text{ARROW}_R) \end{array}$$

Lemma 2.4. *The subterm relation is transitive, i.e. if $\tau \sqsubseteq \delta$, $\delta \sqsubseteq \sigma$ then $\tau \sqsubseteq \sigma$.*

Proof:

Induction on the derivation of $\delta \sqsubseteq \sigma$. □

We define a subterm closure operation on recursive types. As we shall see the subterm closure contains all subterms of a recursive type.

Definition 2.4. The *subterm closure* τ^* of τ is the set of recursive types defined by

$$\begin{array}{ll} \perp^* = \{\perp\} & (\tau_1 \rightarrow \tau_2)^* = \{\tau_1 \rightarrow \tau_2\} \cup \tau_1^* \cup \tau_2^* \\ \top^* = \{\top\} & (\mu\alpha.\tau_1)^* = \{\mu\alpha.\tau_1\} \cup \tau_1^*[\mu\alpha.\tau_1/\alpha] \\ \alpha^* = \{\alpha\} & \end{array}$$

Obviously, the subterm closure is finite; indeed $|\tau^*| = O(|\tau|)$.

Proposition 2.1. $|\tau^*| < \infty$.

An important technical property of the closure operation is its commutation with substitution:

Lemma 2.5. $(\tau'[\tau/\beta])^* = (\tau')^*[\tau/\beta] \cup \tau^*$ if $\beta \in \text{fv}(\tau')$.

Proof:

Induction on the structure of τ' .

Case $\tau' = \beta$: The left-hand side evaluates to

$$(\beta[\tau/\beta])^* = \tau^*$$

and the right-hand side to

$$\beta^*[\tau/\beta] \cup \tau^* = \{\beta\}[\tau/\beta] \cup \tau^* = \{\tau\} \cup \tau^* = \tau^*$$

where we note that $\tau \in \tau^*$.

Case $\tau' = \tau_1 \rightarrow \tau_2$: Since $\beta \in \text{fv}(\tau')$ it must occur free in either τ_1 or τ_2 . The induction hypothesis is then that

$$(\tau_1[\tau/\beta])^* = \tau_1^*[\tau/\beta] \cup \tau^*$$

if $\beta \in \text{fv}(\tau_1)$. Assume that $\beta \in \text{fv}(\tau_2)$.

$$\begin{aligned} & ((\tau_1 \rightarrow \tau_2)[\tau/\beta])^* = \\ & ((\tau_1[\tau/\beta]) \rightarrow \tau_2[\tau/\beta])^* = \\ & \{(\tau_1[\tau/\beta]) \rightarrow \tau_2[\tau/\beta]\} \cup (\tau_1[\tau/\beta])^* \cup (\tau_2[\tau/\beta])^* = \\ & \{\tau_1 \rightarrow \tau_2\}[\tau/\beta] \cup \tau_1^*[\tau/\beta] \cup \tau^* \cup \tau_2^*[\tau/\beta] = \\ & (\{\tau_1 \rightarrow \tau_2\} \cup \tau_1^* \cup \tau_2^*)[\tau/\beta] \cup \tau^* = \\ & (\tau_1 \rightarrow \tau_2)^*[\tau/\beta] \cup \tau^* \end{aligned}$$

The evaluation when $\beta \in \text{fv}(\tau_2)$ is similar.

Case $\tau' = \mu\alpha.\sigma$: We may assume that $\alpha \notin \text{fv}(\tau)$. The induction hypothesis is

$$(\sigma[\tau/\beta])^* = \sigma^*[\tau/\beta] \cup \tau^*.$$

Evaluation of the left-hand side

$$\begin{aligned} & ((\mu\alpha.\sigma)[\tau/\beta])^* = \\ & (\mu\alpha.\sigma[\tau/\beta])^* = \\ & \{\mu\alpha.\sigma[\tau/\beta]\} \cup (\sigma[\tau/\beta])^*[\mu\alpha.\sigma[\tau/\beta]/\alpha] = \\ & \{\mu\alpha.\sigma\}[\tau/\beta] \cup (\sigma^*[\tau/\beta] \cup \tau^*)[\mu\alpha.\sigma[\tau/\beta]/\alpha] = \\ & \{\mu\alpha.\sigma\}[\tau/\beta] \cup \sigma^*[\tau/\beta][\mu\alpha.\sigma[\tau/\beta]/\alpha] \cup \tau^*[\mu\alpha.\sigma[\tau/\beta]/\alpha] = \\ & \{\mu\alpha.\sigma\}[\tau/\beta] \cup \sigma^*[\mu\alpha.\sigma/\alpha][\tau/\beta] \cup \tau^* = \\ & (\{\mu\alpha.\sigma\} \cup \sigma^*[\mu\alpha.\sigma/\alpha])[\tau/\beta] \cup \tau^* = \\ & (\mu\alpha.\sigma)^* \cup \tau^*. \end{aligned}$$

□

Using this property we can show that τ^* contains all syntactic subterms of τ :

Lemma 2.6. *If $\tau \sqsubseteq \sigma$ then $\tau \in \sigma^*$.*

Proof:

Induction on the derivation of $\tau \sqsubseteq \sigma$. The only interesting case is UNFOLD.

Case UNFOLD: So $\sigma = \mu\alpha.\tau'$ and $\tau \sqsubseteq \tau'[\mu\alpha.\tau'/\alpha]$. By IH we get $\tau \in (\tau'[\mu\alpha.\tau'/\alpha])^*$. By Lemma 2.5 substitution and closure commute and we can conclude

$$\tau \in (\tau')^*[\mu\alpha.\tau'/\alpha] \cup (\mu\alpha.\tau')^* = (\mu\alpha.\tau')^*$$

since $(\tau')^*[\mu\alpha.\tau'/\alpha] \subseteq (\mu\alpha.\tau')^*$ by definition of $(\mu\alpha.\tau')^*$.

□

$$|\tau^*| = 1 + |\tau_1^*| + |\tau_2^*| < \infty.$$

Lemma 2.6 and Proposition 2.1 together finally give us the desired property:

Theorem 2.3. *For recursive type τ the set $\{\tau' \mid \tau' \sqsubseteq \tau\}$ is finite.*

Algorithm execution We now study the computations performed by **S**. The main result is that all recursive types encountered in calls to **S** during the computation are syntactic subterms of the initial recursive types. Combined with Theorem 2.3 we can prove that **S** terminates. To reason about the steps performed by **S** we define the notions of call tree and call path.

Definition 2.5. The *call tree* of $\mathbf{S}(A_0, \tau_0, \sigma_0)$ is defined to be a root node labeled $\mathbf{S}(A_0, \tau_0, \sigma_0)$ whose subtrees are the call trees of all the recursive calls $\mathbf{S}(A_i, \tau_i, \sigma_i)$ (finitely many) occurring in the first clause in **S** that matches $\mathbf{S}(A_0, \tau_0, \sigma_0)$.

A *call path* in $\mathbf{S}(A_0, \tau_0, \sigma_0)$ is a path in the call tree of $\mathbf{S}(A_0, \tau_0, \sigma_0)$, starting at its root.

Theorem 2.4. Let τ_0, σ_0 be recursive types and A_0 an assumption set. For all nodes $\mathbf{S}(A_i, \tau_i, \sigma_i)$ in the call tree of $\mathbf{S}(A_0, \tau_0, \sigma_0)$ we have that τ_i, σ_i are syntactic subterms of either τ_0 or σ_0 .

Proof:

Induction on the depth d of nodes.

Case $d = 0$: Root node $\mathbf{S}(A_0, \tau_0, \sigma_0)$. Trivial from reflexivity of \sqsubseteq .

Case $d > 0$: Case analysis of nodes at depth $d - 1$.

Case $\mathbf{S}(A, \mu\alpha.\tau, \sigma)$: The unique child of $\mathbf{S}(A, \mu\alpha.\tau, \sigma)$ at depth d is $\mathbf{S}(A, \tau[\mu\alpha.\tau/\alpha], \sigma)$. By induction hypothesis we know that $\mu\alpha.\tau$ and σ are in canonical form and furthermore that

$$(\mu\alpha.\tau \sqsubseteq \tau_0 \wedge \sigma \sqsubseteq \sigma_0) \quad \text{or} \quad (\mu\alpha.\tau \sqsubseteq \sigma_0 \wedge \sigma_i \sqsubseteq \tau_0).$$

It is easily seen that $\tau[\mu\alpha.\tau/\alpha]$ is in canonical form. Assume $\mu\alpha.\tau \sqsubseteq \tau_0 \wedge \sigma \sqsubseteq \sigma_0$. By Rule UNFOLD we have $\tau[\mu\alpha.\tau/\alpha] \sqsubseteq \mu\alpha.\tau$ and thus by transitivity (Lemma 2.4) $\tau[\mu\alpha.\tau/\alpha] \sqsubseteq \tau_0$. The other subcase, $\mu\alpha.\tau \sqsubseteq \sigma_0 \wedge \sigma_i \sqsubseteq \tau_0$, is similar.

Case $\mathbf{S}(A, \tau, \mu\beta.\sigma)$: Analogous to the above case.

Case $\mathbf{S}(A, \tau_1 \rightarrow \tau_2, \sigma_1 \rightarrow \sigma_2)$: There are two child nodes at depth d :

1. $\mathbf{S}(A', \sigma_1, \tau_1)$. By IH we know that $\tau_1 \rightarrow \tau_2 \sqsubseteq \tau_0$ and $\sigma_1 \rightarrow \sigma_2 \sqsubseteq \sigma_0$, or $\tau_1 \rightarrow \tau_2 \sqsubseteq \sigma_0$ and $\sigma_1 \rightarrow \sigma_2 \sqsubseteq \tau_0$. But then the result follows directly from transitivity (Lemma 2.4) since $\tau_1 \sqsubseteq \tau_1 \rightarrow \tau_2$ and $\sigma_1 \sqsubseteq \sigma_1 \rightarrow \sigma_2$ by Rule ARROW_L.
2. $\mathbf{S}(A', \tau_2, \sigma_2)$. Exactly as previous case.

□

Lemma 2.7. For any call path $\mathbf{S}(A_0, \tau_0, \sigma_0), \dots, \mathbf{S}(A_i, \tau_i, \sigma_i), \dots$ of $\mathbf{S}(A_0, \tau_0, \sigma_0)$ we have

$$A_0 \subseteq A_1 \subseteq \dots \subseteq A_i \subseteq \dots$$

Proof:

By inspection of Algorithm **S** we see that, for every clause $\mathbf{S}(A, \tau, \sigma)$ and every recursive call $\mathbf{S}(A', \tau', \sigma')$ occurring in it, we have $A \subseteq A'$. □

Lemma 2.8. *For any call path $\mathbf{S}(A_0, \tau_0, \sigma_0), \dots, \mathbf{S}(A_n, \tau_n, \sigma_n), \dots$ of $\mathbf{S}(A_0, \tau_0, \sigma_0)$ we have*

$$\exists N. \forall i. (\tau_i, \sigma_i) \in \left\{ (\tau_j, \sigma_j) \mid 0 \leq j \leq N \right\}.$$

The lemma states that every path has only finitely many different type arguments.

Proof:

The statement is proved by contradiction. Assume that

$$\forall N \exists i : (\tau_i, \sigma_i) \notin \left\{ (\tau_j, \sigma_j) \mid 0 \leq j \leq N \right\}$$

This fact directly implies that $\{(\tau_j, \sigma_j) \mid j \in \mathbb{N}_0\}$ is an infinite set. Theorem 2.4 states that all terms in a call tree are subterms of the initial two terms. We thus have

$$\{(\tau_j, \sigma_j) \mid j \in \mathbb{N}_0\} \subseteq (\{\tau_j \mid j \in \mathbb{N}_0\}) \times (\{\sigma_j \mid j \in \mathbb{N}_0\}) \subseteq (\{\tau \mid \tau \sqsubseteq \tau_0\} \cup \{\sigma \mid \sigma \sqsubseteq \sigma_0\})^2$$

Theorem 2.3, however, implies that

$$|\{(\tau_j, \sigma_j) \mid j \in \mathbb{N}_0\}| \leq |\{\tau \mid \tau \sqsubseteq \tau_0\} \cup \{\sigma \mid \sigma \sqsubseteq \sigma_0\}|^2 < \infty$$

which contradicts our assumption that $\{(\tau_j, \sigma_j) \mid j \in \mathbb{N}_0\}$ is infinite. \square

The above results enable us to prove termination of \mathbf{S} .

Theorem 2.5. (Termination of \mathbf{S}) *If τ, σ are canonical and A is an assumption set then $\mathbf{S}(A, \tau, \sigma)$ terminates.*

Proof:

The proof is once again by contradiction. Assume that $\mathbf{S}(A, \tau, \sigma)$ does not terminate, i.e. there exists an infinite call path p in the call tree of $\mathbf{S}(A, \tau, \sigma)$. Let N be determined by Lemma 2.8 such that

$$\forall i : (\tau_i, \sigma_i) \in \left\{ (\tau_j, \sigma_j) \mid 0 \leq j \leq N \right\} \tag{1}$$

Let us consider the calls (τ_i, σ_i) of p where $i > N$. There must exist a call (τ_n, σ_n) with $n > N$ where $\tau_n = \tau_1 \rightarrow \tau_2$ and $\sigma_n = \sigma_1 \rightarrow \sigma_2$, because otherwise all calls would be unfoldings, which is not possible since the terms are in canonical form (Theorem 2.4). From (1) we conclude that $(\tau_1 \rightarrow \tau_2, \sigma_1 \rightarrow \sigma_2) \in \{(\tau_j, \sigma_j) \mid 0 \leq j \leq N\}$ which implies that there exists $m \leq N < n$ such that $(\tau_n, \sigma_n) = (\tau_m, \sigma_m)$. The assumption set associated with call n inherits all assumptions from its ancestors in p (by Lemma 2.7), but then call n must be an application of HYP, which corresponds to a leaf in the call tree. Path p is therefore not infinite and the assumption is false. \square

2.3.3. Correctness of S

Finally we show that, whenever $\tau \leq_{AC} \sigma$, $\mathbf{S}(A, \tau, \sigma)$ does not fail (i.e. it does not raise an exception) and it returns a proof of $A \vdash \tau \leq \sigma$.

Lemma 2.9. *Let τ, σ be recursive types in canonical form and A an assumption set. If $\tau \leq_{AC} \sigma$ then $\mathbf{S}(A, \tau, \sigma)$ returns a derivation of $A \vdash \tau \leq \sigma$.*

Proof:

The termination theorem (Theorem 2.5) gives that $\mathbf{S}(A, \tau, \sigma)$ terminates with, say, n recursive calls. Correctness is proved by induction on n . In each case we verify the derivation returned by \mathbf{S} .

Case $n = 0$. No recursive calls performed at all. We perform a case analysis on those clauses in \mathbf{S} that have no recursive calls.

Case $\mathbf{S}((A, \tau \leq \sigma, A'), \tau, \sigma)$, $\mathbf{S}(A, \alpha, \alpha)$, $\mathbf{S}(A, \perp, \tau)$ or $\mathbf{S}(A, \tau, \top)$: Obvious.

Case $\mathbf{S}(A, \tau, \sigma)$: If this clause is reached, it means that $\mathcal{L}(\tau) \neq \perp$, $\mathcal{L}(\sigma) \neq \top$ and $\mathcal{L}(\tau) \neq \mathcal{L}(\sigma)$, i.e. $\mathcal{L}(\tau) \not\leq \mathcal{L}(\sigma)$. Since \leq_{AC} is a simulation and $\tau \leq_{AC} \sigma$ it must hold that $\mathcal{L}(\tau) \leq \mathcal{L}(\sigma)$, which contradicts $\mathcal{L}(\tau) \not\leq \mathcal{L}(\sigma)$. Thus this clause is never reached.

Case $n > 0$. Our induction hypothesis is that computations $\mathbf{S}(A', \tau', \sigma')$ with fewer than n recursive calls, where $\tau' \leq_{AC} \sigma'$, produce a correct derivation of $A' \vdash \tau' \leq \sigma'$. We perform a case analysis of rules containing recursive calls.

Case $\mathbf{S}(A, \mu\alpha.\tau, \sigma)$: Since \leq_{AC} is a simulation (Lemma 2.1) we have $\tau[\mu\alpha.\tau/\alpha] \leq_{AC} \sigma$. Thus the induction hypothesis applies and gives that $\mathbf{S}(A, \tau[\mu\alpha.\tau/\alpha], \sigma)$ returns a derivation of $A \vdash \tau[\mu\alpha.\tau/\alpha] \leq \sigma$. By UNFOLD and TRANS we then get a proof of $A \vdash \mu\alpha.\tau \leq \sigma$, which is exactly what $\mathbf{S}(A, \mu\alpha.\tau, \sigma)$ returns.

Case $\mathbf{S}(A, \tau, \mu\beta.\sigma)$: Since \leq_{AC} is a simulation (Lemma 2.1) we get $\tau \leq_{AC} \sigma[\mu\beta.\sigma/\beta]$. Thus the induction hypothesis is applicable and gives that $\mathbf{S}(A, \tau, \sigma[\mu\beta.\sigma/\beta])$ returns a proof of $A \vdash \tau \leq \sigma[\mu\beta.\sigma/\beta]$. We conclude

$$\frac{\frac{\text{(IH)}}{A \vdash \tau \leq \sigma[\mu\beta.\sigma/\beta]} \quad \frac{\text{(FOLD)}}{A \vdash \sigma[\mu\beta.\sigma/\beta] \leq \mu\beta.\sigma}}{A \vdash \tau \leq \mu\beta.\sigma} \text{(TRANS)}$$

which is the result of $\mathbf{S}(A, \tau, \mu\beta.\sigma)$.

Case $\mathbf{S}(A, \tau_1 \rightarrow \tau_2, \sigma_1 \rightarrow \sigma_2)$: Let $A' = A \cup \{\tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2\}$. Two recursive calls are issued from this rule.

1. $\mathbf{S}(A', \sigma_1, \tau_1)$. From the simulation property of \leq_{AC} and IH we get that the call returns a proof of $A' \vdash \sigma_1 \leq \tau_1$.

2. $\mathbf{S}(A', \tau_2, \sigma_2)$. As above, the call returns a proof of $A' \vdash \tau_2 \leq \sigma_2$.

Consequently, $\mathbf{S}(A, \tau_1 \rightarrow \tau_2, \sigma_1 \rightarrow \sigma_2)$ returns Rule ARROW/FIX applied to the two subproofs above, which is a proof of $A \vdash \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2$. □

Theorem 2.6. (Completeness) *If $\tau \leq_{\text{AC}} \sigma$ then $\vdash \tau \leq \sigma$.*

Proof:

Follows from Lemma 2.9 for $A = \emptyset$. □

3. Proofs as Coercions

In this section we present a somewhat generalized axiomatization of recursive subtyping in which rules ARROW and FIX are separated instead of being melded into a single rule as in Figure 3. This is made possible by using an explicit term representation of proofs as *coercions*. Sound application of Rule FIX is then guaranteed by requiring the coercion in the premise to be formally *contractive* in a sense to be defined. The coercion constructions for the rules in the axiomatization can be interpreted as natural functional programming constructs. Notably, the fixpoint rule corresponds to definition by recursion. Coercions can then be used as a basis for *proof theory* as well as *operational interpretation* of proofs in the sense of the Curry-Howard isomorphism.

The latter is important where coercions are not only (constructive) evidence of some subsumption relation, but have semantic significance; that is, they denote functions that map an element of one type to an element of its supertype. Furthermore, coercions may have *operational significance*; that is, different proofs of the *same* subtyping statement may yield coercions with different operational characteristics. For example, folding and unfolding to and from a recursive type (corresponding to the axioms $A \vdash \tau[\mu\alpha.\tau/\alpha] \leq \mu\alpha.\tau$ and $A \vdash \mu\alpha.\tau \leq \tau[\mu\alpha.\tau/\alpha]$, respectively) may operationally require execution of a referencing (heap allocation) and (pointer) dereferencing step, respectively. In this case it is a good idea to replace their composition by the identity coercion (corresponding to the axiom of reflexivity), since the latter is obviously operationally more efficient than the former.

In a separate paper we shall explore the semantics and operational interpretation of coercions. Here we shall only briefly describe their operational interpretation in order to demonstrate, in intuitive and nontechnical terms, how each rule corresponds to a natural program construct.

3.1. Coercions and their functional interpretation

Coercions are defined by the grammar

$$C := \iota_\tau \mid f \mid \mathbf{fix} \ f : \tau \leq \tau'.c \mid c; c \mid c \rightarrow c \mid \text{fold}_{\mu\alpha.\tau} \mid \text{unfold}_{\mu\alpha.\tau} \mid \text{abort}_\tau \mid \text{discard}_\tau$$

Each coercion can be interpreted as a function:

- ι_τ denotes the identity on type τ .
- $\mathbf{fix} f : \tau \leq \tau'. c$ denotes the function f recursively defined by the equation $f = c$ (note that f may occur in c).
- $c; c'$ denotes the composition of c' with c .
- $c \rightarrow c'$ denotes the functional F defined by $Ffx = c'(f(cx))$.
- The pair $\text{fold}_{\mu\alpha.\tau}$ and $\text{unfold}_{\mu\alpha.\tau}$ denotes the isomorphism between $\tau[\mu\alpha.\tau/\alpha]$ and $\mu\alpha.\tau$.
- Both \perp and \top denote 1, the single point domain whose sole element we denote by \perp_1 . We can think of 1 as containing only nonterminating computations, no real value. Then abort_τ maps any argument to a nonterminating computation at type τ and discard_τ maps any argument to a nonterminating computation at type \perp ; that is, operationally both abort_τ and discard_τ simply enter an infinite loop for any argument.

Alternatively, we can think of 1 as containing the single value $()$ and make sure that there are no nonterminating computations at \perp or \top . This is simple, however, since, operationally, we can evaluate any expression of type \perp or \top by immediately returning $()$.

3.2. Well-typed coercions

Definition 3.1. (Contractiveness) A coercion c is *(formally) contractive* in coercion variable f if one of the following conditions holds:

1. f does not occur in c .
2. $c \equiv c_1 \rightarrow c_2$.
3. $c \equiv c_1; c_2$ and both c_1 and c_2 are contractive in f .
4. $c \equiv \mathbf{fix} g : \tau \leq \sigma. c_1$ and c_1 is contractive in f .

Definition 3.2. (Well-typed coercions, canonical coercions) Coercion c is *well-typed* if $E \vdash c : \tau \leq \sigma$ is derivable for some E, τ, σ in the inference system of Figure 6.

A well-typed coercion c is *canonical* if every \mathbf{fix} -coercion occurring in c has the form $\mathbf{fix} f : \tau' \leq \sigma'. c_1 \rightarrow c_2$.

Thinking of coercions as a special class of functions, \leq can be understood as a special (coercion) type constructor in Figure 6. Assumptions in E are of the form $f : \tau \leq \sigma$ where coercion variable f occurs at most once in E . Note that the subscripting of coercions guarantees that there is exactly one proof for every derivable $E \vdash c : \tau \leq \sigma$. Let us write \bar{E} for the subtyping assumptions we get from E by erasing all coercion variables in it.

Well-typed coercions are a term interpretation of the axiomatization in Figure 3 in the sense that for every E and every proof of $\bar{E} \vdash \tau \leq \tau'$ there exists a unique canonical coercion c such that $E \vdash c : \tau \leq \tau'$, where every coercion of the form $c_1 \rightarrow c_2$ is the body of some \mathbf{fix} -coercion. Conversely, it is easily seen that every canonical coercion of this form corresponds to a proof using the inference rules of Figure 3.

Theorem 3.1. *We have $\vdash \tau \leq \tau'$ if and only if there exists a canonical coercion c such that $\vdash c : \tau \leq \tau'$.*

$$E \vdash \iota_\tau : \tau \leq \tau$$

$$E \vdash \text{abort}_\tau : \perp \leq \tau$$

$$E \vdash \text{discard}_\tau : \tau \leq \top$$

$$E \vdash \text{unfold}_{\mu\alpha.\tau} : \mu\alpha.\tau \leq \tau[\mu\alpha.\tau/\alpha] \quad E \vdash \text{fold}_{\mu\alpha.\tau} : \tau[\mu\alpha.\tau/\alpha] \leq \mu\alpha.\tau$$

$$\frac{E \vdash c : \tau \leq \delta \quad E \vdash d : \delta \leq \sigma}{E \vdash c; d : \tau \leq \sigma}$$

$$\frac{E \vdash c : \tau \leq \tau' \quad , \quad d : \sigma \leq \sigma'}{E \vdash (c \rightarrow d) : (\tau' \rightarrow \sigma) \leq (\tau \rightarrow \sigma')}$$

$$E, f : \tau \leq \sigma, E' \vdash f : \tau \leq \sigma$$

$$\frac{E, f : \tau \leq \sigma \vdash c_f : \tau \leq \sigma \quad c_f \text{ contr. in } f}{E \vdash \mathbf{fix} f : \tau \leq \sigma. c_f : \tau \leq \sigma}$$

Figure 6. Coercion typing rules

Proof:

“Only if” is obvious. Let $\vdash c : \tau \leq \tau'$. “If” follows from the observation that every coercion occurrence of the form $c_1 \rightarrow c_2$ can be “wrapped” with $\mathbf{fix} f : \sigma \leq \sigma'$ (f fresh) for suitable recursive types σ, σ' if it is not already the body of a \mathbf{fix} -coercion. Once this is done, the transformed coercion corresponds directly to a derivation in Figure 3. \square

This theorem holds not only for *canonical* coercions, but also for the larger class of *well-typed* coercions; that is, well-typed coercions give more *proofs*, but not more *theorems* than canonical coercions. Since this requires a rather lengthy and involved proof, however, we omit it here.

4. From coinductive definition to inductive definition

In this section we take a more general look at axiomatizing coinductively defined sets. In particular, we shall justify why we have called our axiomatization *coinductive* and why we refer to the fixpoint rule also as a *coinduction principle*. Our purpose is to present the general ideas, exemplified by transforming a coinductive definition of Amadio/Cardelli-subtyping systematically to an axiomatization featuring the fixpoint rule \mathbf{FIX} . That axiomatization is similar, but not identical to the ones presented in the previous sections. The transformation is intended to shed insight into the role of formal contractiveness and the way the fixpoint rule embodies a minimal, finitary coinduction principle. No proofs are given since corresponding results have been established in the previous sections.

$$\begin{array}{c}
\vdash \perp \leq \tau \quad (\perp) \qquad \qquad \qquad \vdash \tau \leq \top \quad (\top) \\
\\

Figure 7. Normalized subtyping inference rules

4.1. Coinductive characterization of Amadio/Cardelli subtyping

A set S is *coinductively definable*, or simply *coinductive*, if it is the greatest fixpoint of a monotonic operator \mathcal{F} under set containment: $S = \bigcup \{X \mid X \subseteq \mathcal{F}(X)\}$. The *coinduction principle* says that, in order to prove that $P \subseteq S$ it is sufficient to prove $P \subseteq \mathcal{F}(P)$.

Every inference system I , viewed as a rule system in the sense of Aczel [Acz77], gives rise to a monotonic operator \mathcal{F}_I . Consider the inference system I_{\leq} in Figure 7. Its associated operator \mathcal{F}_{\leq} maps sets of pairs of recursive types to sets of pairs of recursive types.

We define \leq_{\min} to be the set of pairs (τ, σ) such that there exists a derivation of $\vdash \tau \leq \sigma$. Equivalently, we can define \leq_{\min} as the least fixpoint of \mathcal{F}_{\leq} :

$$\leq_{\min} = \text{lfp } \mathcal{F}_{\leq} = \bigcap \{R \mid \mathcal{F}_{\leq}(R) \subseteq R\}.$$

Let us call \leq_{\min} *weak subtyping* in analogy with weak type equality. (Indeed, if we strike out the rules \perp and \top we arrive at an axiomatization of weak type equality.)

The set \leq_{\max} *coinductively* defined by I_{\leq} is the greatest fixpoint of \mathcal{F}_{\leq} :

$$\leq_{\max} = \text{gfp } \mathcal{F}_{\leq} = \bigcup \{R \mid R \subseteq \mathcal{F}_{\leq}(R)\}.$$

Note that \leq_{\max} properly contains \leq_{\min} ; in particular, not every pair in \leq_{\max} has a finite derivation in I_{\leq} . Aczel calls \leq_{\min} the *set inductively defined by I_{\leq}* [Acz77, Section 1.1] and \leq_{\max} the *kernel of I_{\leq}* [Acz77, Section 1.6].

Theorem 4.1. $(\tau, \sigma) \in \leq_{\max}$ if and only if $\tau \leq_{\text{AC}} \sigma$.

This theorem expresses that Amadio/Cardelli subtyping is definable by the inference system I_{\leq} , though under its *coinductive* interpretation, not its standard inductive interpretation.

4.2. Infinitary axiomatization of Amadio/Cardelli subtyping

We can internalize the coinductive nature of \leq_{AC} as follows: To prove that $\tau \leq_{\text{AC}} \sigma$ find a set of *subtyping hypotheses* R such that:

$$R \vdash \perp \leq \tau \quad (\perp)$$

$$R \vdash \tau \leq \top \quad (\top)$$

$$R \vdash \tau \leq \tau \quad (\text{REF})$$

$$\frac{R \vdash \sigma_1 \leq \tau_1 \quad R \vdash \tau_2 \leq \sigma_2}{R \vdash \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2} \quad (\text{ARROW})$$

$$\frac{R \vdash \tau[\mu\alpha.\tau/\alpha] \leq \sigma}{R \vdash \mu\alpha.\tau \leq \sigma} \quad (\text{UNFOLD}')$$

$$\frac{R \vdash \sigma \leq \tau[\mu\alpha.\tau/\alpha]}{R \vdash \sigma \leq \mu\alpha.\tau} \quad (\text{FOLD}')$$

$$\frac{R \vdash^+ R}{\vdash R} \quad (\text{COIND})$$

$$R \cup \{\tau \leq \sigma\} \vdash \tau \leq \sigma \quad (\text{HYP})$$

$$\frac{R \vdash P \cup \{\tau \leq \sigma\}}{R \vdash \tau \leq \sigma} \quad (\wedge\text{-ELIM})$$

$$\frac{R \vdash \tau \leq \sigma \quad (\forall(\tau \leq \sigma) \in P)}{R \vdash P} \quad (\wedge\text{-INTRO})$$

Figure 8. Normalized subtyping inference rules with coinduction principle

1. $(\tau, \sigma) \in R$, and
2. $R \subseteq \mathcal{F}_{\leq}(R)$

This is obviously a *sound and complete* proof principle for Amadio/Cardelli subtyping since we can choose $R = \leq_{\text{AC}}$.

Since $X = \mathcal{F}_{\leq}(X) \cup \dots \cup F_{\leq}^i(X) \dots$ for any fixed point of \mathcal{F}_{\leq} we can replace the second condition by the following rule-based coinduction principle:

- 2'. $R \vdash^+ \tau' \leq \sigma'$ for all $\tau' \leq \sigma' \in R$.

Here $R \vdash^+ \tau' \leq \sigma'$ means that $\tau' \leq \sigma'$ is derivable from I_{\leq} and the hypotheses R , using *at least one* instance of an inference rule in I_{\leq} . We say that a proof is *formally contractive* if it contains at least one application of one of the inference rules; that is, a formally contractive proof must not simply consist of a single invocation of one of the hypotheses.

We can add the coinduction principle as an *infinitary* inference rule to I_{\leq} ; see Figure 8. Here the notation \vdash^+ in Rule COIND expresses that $R \vdash \tau \leq \sigma$ must have a formally contractive proof for each $\tau \leq \sigma \in R$; that is, the last step applied to prove each of the subtyping premises in R must *not* be by Rule HYP. At the cost of introducing judgements with potentially infinite *sets* of subtypings and the infinitary rule \wedge -INTRO this inference system is sound and complete for deriving \leq_{AC} -subtypings: $\tau \leq_{\text{AC}} \sigma$ if and only if there exists a derivation of $\vdash \tau \leq \sigma$ in the inference system of Figure 8.

4.3. Finitary coinduction principle

We shall now show how we can get rid of infinite sets of subtypings and finally sets of subtypings altogether. This eventually results in an axiomatization similar to the one in Figure 6. The key

$$E \vdash \text{abort}_\tau : \perp \leq \tau$$

$$E \vdash \text{discard}_\tau : \tau \leq \top$$

$$E \vdash \iota_\tau : \tau \leq \tau$$

$$\frac{E \vdash c : \sigma_1 \leq \tau_1 \quad E \vdash d : \tau_2 \leq \sigma_2}{E \vdash c \rightarrow d : \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2}$$

$$\frac{E \vdash c : \tau[\mu\alpha.\tau/\alpha] \leq \sigma}{E \vdash (\text{unfold}_{\mu\alpha.\tau}; c) : \mu\alpha.\tau \leq \sigma}$$

$$\frac{E \vdash d : \sigma \leq \tau[\mu\alpha.\tau/\alpha]}{E \vdash (d; \text{fold}_{\mu\alpha.\tau}) : \sigma \leq \mu\alpha.\tau}$$

$$E_1, f : \tau \leq \sigma, E_2 \vdash f : \tau \leq \sigma \quad (\text{HYP})$$

$$\frac{f_1 : \tau_1 \leq \sigma_1, \dots, f_n : \tau_n \leq \sigma_n \vdash (c_1, \dots, c_n) : \tau_1 \leq \sigma_1 \wedge \dots \wedge \tau_n \leq \sigma_n}{\vdash \mathbf{fix}(f_1 : \tau_1 \leq \sigma_1, \dots, f_n : \tau_n \leq \sigma_n).(c_1, \dots, c_n) : \tau_1 \leq \sigma_1 \wedge \dots \wedge \tau_n \leq \sigma_n} \quad (\text{COIND})$$

$$\frac{E \vdash c : \tau_1 \leq \sigma_1 \wedge \dots \wedge \tau_n \leq \sigma_n}{E \vdash c.i : \tau_i \leq \sigma_i} \quad (\wedge\text{-ELIM})$$

$$\frac{E \vdash c_1 : \tau_1 \leq \sigma_1 \dots E \vdash c_n : \tau_n \leq \sigma_n}{E \vdash (c_1, \dots, c_n) : \tau_1 \leq \sigma_1 \wedge \dots \wedge \tau_n \leq \sigma_n} \quad (\wedge\text{-INTRO})$$

Figure 9. Normalized subtyping inference rules with finitary coinduction principle

property we require is that \leq_{AC} is finitary in the following sense.

Theorem 4.2. $\tau \leq_{\text{AC}} \sigma$ if and only if there exists a finite R such that:

1. $(\tau, \sigma) \in R$ and
2. $R \subseteq \mathcal{F}_{\leq}(R)$.

We can think of such an R as a (finite) witness to the fact that $\tau \leq_{\text{AC}} \sigma$ for any $(\tau, \sigma) \in R$. (This proposition also holds if we replace the second condition by requiring that R be a simulation. Note, however, that $R \subseteq \mathcal{F}_{\leq}(R)$ for every simulation R , but not every R such that $R \subseteq \mathcal{F}_{\leq}(R)$ is a simulation.) An immediate consequence is that the inference system in Figure 8 remains complete when restricted to *finite* sets of subtypings both to the left and to the right of the turnstile. We can thus treat sets of subtypings as *finite conjunctions* of subtypings.

Figure 9 gives the resulting inference system. We have added explicit proof terms to suggest a natural operational interpretation of proofs as coercions. In particular, the coinduction principle is interpreted as a finite tuple of functions that are mutually recursively defined. Formal contractiveness is captured by requiring that in Rule COIND none of the c_i must be a coercion variable f_j .

$$E \vdash \text{abort}_\tau : \perp \leq \tau \quad (\perp)$$

$$E \vdash \text{discard}_\tau : \tau \leq \top \quad (\top)$$

$$E \vdash \iota_\tau : \tau \leq \tau \quad (\text{REF})$$

$$\frac{E \vdash c : \sigma_1 \leq \tau_1 \quad E \vdash d : \tau_2 \leq \sigma_2}{E \vdash c \rightarrow d : \tau_1 \rightarrow \tau_2 \leq \sigma_1 \rightarrow \sigma_2} \quad (\text{ARROW})$$

$$\frac{E \vdash c : \tau[\mu\alpha.\tau/\alpha] \leq \sigma}{E \vdash \text{unfold}_{\mu\alpha.\tau}; c : \mu\alpha.\tau \leq \sigma} \quad (\text{UNFOLD}')$$

$$\frac{E \vdash d : \sigma \leq \tau[\mu\alpha.\tau/\alpha]}{E \vdash d; \text{fold}_{\mu\alpha.\tau} : \sigma \leq \mu\alpha.\tau} \quad (\text{FOLD}')$$

$$\frac{E, f : \tau \leq \sigma \vdash c : \tau \leq \sigma}{E \vdash \mathbf{fix} f : \tau \leq \sigma. c : \tau \leq \sigma} \quad (\text{FIX})$$

$$E_1, f : \tau \leq \sigma, E_2 \vdash f : \tau \leq \sigma \quad (\text{HYP})$$

Figure 10. Normalized subtyping inference rules with Fixpoint Rule

4.4. Gaussian elimination

The coercion interpretation of the coinduction principle in Figure 9 suggests how we can simplify the coinduction principle even further, without losing completeness. The term formulation of this proof rule reveals that it corresponds to (closed) mutually recursive definitions of coercions. Using Gaussian elimination, as in Bekic's Theorem, mutually recursive definitions can be eliminated and replaced by nested, not necessarily closed, directly recursive definitions. (Note that the above observation amounts to a proof-theoretic application of Gaussian elimination.) Thus we can restrict the inference system even further without losing completeness: we replace Rule COIND by Rule FIX.

$$\frac{E, f : \tau \leq \sigma \vdash c : \tau \leq \sigma}{E \vdash \mathbf{fix} f : \tau \leq \sigma. c : \tau \leq \sigma} \quad (\text{FIX})$$

where c must not be a coercion variable. Now the introduction and elimination rules for conjunctions are superfluous for deriving judgements of the form $E \vdash \tau \leq \sigma$ and can be eliminated completely. We end up with the inference system displayed in Figure 10. Note that this is the inference system I_{\leq} of Figure 7, enhanced with finite lists of subtyping assumptions and the attendant rule for invoking hypotheses, plus a single additional rule: the fixpoint rule.

5. Conclusion

5.1. Summary

We have given sound and complete axiomatizations of type equality and type containment using a novel fixpoint rule, Rule FIX. The fixpoint rule can be viewed as embodying a form of coinduction principle. It gives rise to a natural interpretation of proofs as coercions where the

fixpoint rule corresponds to definition by recursion. Finally, we have discussed how coinductively defined sets can be turned into inductively defined ones using the fixpoint rule.

5.2. Related work

5.2.1. Recursive type equality and subtyping

The present work was inspired by an observation that meant that the standard unification closure algorithm [HK71, Hue76] (see [ASU86, Section 6.7] for a presentation) can be turned into an axiomatization of recursive type equality simply by “adding” the type equation to be proved to the assumptions in the premises; see Figure 4. Unification closure works by building a bisimulation between two recursive types. This suggested early on considering recursive type equality and recursive subtyping as coinductive notions characterized by finitary notions of bisimulation and simulation, respectively. Fiore [Fio96] has made the semantic connections between bisimulation, final coalgebras, attendant coinduction principles and equality of infinite trees precise in a category-theoretic setting.

Amadio and Cardelli [AC91, AC93] have defined subtyping for recursive types and given an axiomatization inspired by work relying on the CONTRACT Rule [Sal66, Mil84]. They also present an “algorithm”, which is the basis for efficient subtype checking and can be understood as an inference system based on a finitary coinduction principle (analogous to Figure 9, though without an operational interpretation). In contrast to our work the types $\mu\alpha.\tau$ and $\tau[\mu\alpha.\tau/\alpha]$ are *identified* in their work, which is tantamount to saying that the syntactic objects they operate on are regular trees and, operationally, coercing between $\mu\alpha.\tau$ and $\tau[\mu\alpha.\tau/\alpha]$ is a “no-op”. In contrast, we treat $\mu\alpha.\tau$ and $\tau[\mu\alpha.\tau/\alpha]$ as distinct syntactic objects that are semantically and operationally related by a unique *isomorphism*, corresponding to the interpretation of the pair of inference rules FOLD and UNFOLD. In particular, coercions need not be interpreted by the identity. In this fashion we can model $\mu\alpha.\tau$ and $\tau[\mu\alpha.\tau/\alpha]$ as different data type representations that can be used interchangeably, though at the cost of applying a coercion.

Abadi and Fiore develop a semantic interpretation of recursive type equality as isomorphisms by induction on the axiomatization given by Amadio and Cardelli [AC93]. They use this interpretation to relate the semantics of FPC [Gun92] under identification of recursive type equality to its semantics under isomorphism. Our coinductive axiomatization of recursive type equality gives rise to an operational interpretation of type equalities as coercions (not pairs of coercions). In our setting, there is semantically at most one coercion between any two types and consequently — semantically — exactly one admissible isomorphism between isomorphic types. In contrast, Abadi and Fiore consider all possible isomorphisms between types. They are thus not restricted to single isomorphisms nor forced to characterize these in a particular fashion. However, this generality seems to cause a problem with the semantic soundness of the CONTRACT rule.

5.2.2. Program logic

The fixpoint rule in its term form (see Rule FIX in Figure 6), is well known as a reasoning principle for proving partial correctness [Hoa70] and, in suitably adapted form, total correctness [Sok77, Nie85] of recursive procedures. In a denotational setting the fixpoint rule corresponds to the principle of Scott induction and is valid for so-called inclusive (also called admissible) relations, which can be thought of as the semantic analogue to partial correctness predicates.

Note that in program logic we start with a program and wish to prove properties about it, using (the term formulation of) the fixpoint rule, amongst other reasoning principles. In contrast to this we have arrived at the recursive definition interpretation of the fixpoint rule from the other direction: we have shown that a finitary coinductive set can be captured inductively using the fixpoint rule and, furthermore, every *element* in the set can be given a natural operational interpretation by interpreting the fixpoint rule as a recursive definition. We claim that one of our conceptual contributions is not only the fixpoint rule itself for reasoning about coinductive sets, but also the fact that its correct semantic interpretation is as the (least) fixed points of recursive definitions [Bra97].

5.2.3. Type theory

Coquand [Coq93] formulates a *guarded induction principle* for reasoning about infinite objects within Type Theory. Using Coquand’s terminology, an expression of some ground datatype is a *productive element* if, intuitively, it reduces to a constructor applied to a list of expressions, and each of these expressions is recursively productive. In this sense a productive element can be said to describe a potentially infinite tree without “undefined” (nonterminating) subtrees. An expression of higher type is *reducible* if it is hereditarily productive; e.g. function $f : A \rightarrow B$ is reducible for data types A, B if it maps every productive element of A to a productive element of B . Requiring expressions to be reducible guarantees consistency since no nonterminating expressions can be defined. A (first-order) recursive definition $f(x_1, \dots, x_n) = e[f, x_1, \dots, x_n]$ is *guarded* if every occurrence of f has arguments that do not contain occurrences of f , and f occurs “under” at least one constructor. Every function definable by guarded recursion is reducible. Thus guarded recursion yields a sound reasoning principle, called guarded induction by Coquand.

Our fixpoint rule and its contractiveness requirement seem to be a close pendant to Coquand’s induction principle and its guardedness requirement. A careful and precise comparison, however, remains to be done. On a more speculative note, both Coquand’s and our work can be viewed as making steps towards extending the Curry-Howard program to recursively defined proofs and recursively defined propositions.

5.2.4. Coinductive reasoning

Observational congruence [Mor68] of programs is intuitively a coinductive notion since — disregarding nontermination for now — its dual, noncongruence, is an inductive, finitary notion:

two expressions are observationally noncongruent if there is a finite experiment under which the two expressions give different, observable answers. It is thus not surprising that coinduction principles play an important role in proving program properties such as program equivalences [MT91, Gor95, HL95, Len96]. Indeed for many programming languages observational congruence can be characterized by a notion of bisimulation; see e.g. [Mil77, Abr90]. This means that, both in theory and practice, observational congruences can be proved by establishing bisimulations based directly on the operational semantics of a language. These bisimulations are usually neither finitary — quite the opposite — nor do they have, suggest or require operational significance.

5.3. Future work

5.3.1. Semantics and operational interpretation of coercions

In continuation of the work reported here we have formulated an equational theory of coercions that is complete in the sense that two coercions are provably equal if and only if they have identical type signatures [Bra97]. Interestingly, this theory is coinductive, too, as it is based on the fixpoint rule, though for coercion equalities instead of type equalities or subtypings. We show that the equational theory is verified in a standard denotational (cpo-based) interpretation of coercions. This shows that, extensionally, any two coercions with the same type signature are equivalent. Conversely, the equational theory codifies the requirements on a semantics of coercions if we demand that any two coercions be extensionally equivalent.

The equational theory can be used as a starting point for optimization of coercions by rewriting. Even though coercions of equal type signature are extensionally equivalent, they are not necessarily equally *efficient*. By viewing some of the coercion equations as operational inequalities, we can show that operationally optimal coercions exist, are unique modulo the remaining equalities and can be generated efficiently [Bra97].

5.3.2. Coercion theory for simply typed λ -calculus with recursive types

We would like to extend the equational theory for coercions to the typed lambda calculus with embedded coercions in the style of [BTCGS91, CG90, Hen94, Reh95] in order to obtain a general coherence characterization for simply typed lambda-calculus with recursive subtyping. This should give another approach to comparing the semantics of FPC under type equality on the one hand and under type isomorphism on the other hand [AF96].

5.3.3. Other coinduction axiomatizations

Other coinductively defined relations should be amenable to the program laid out in Section 4; for example, regular Böhm tree equality [Hue96] and regular expression equality [Sal66, Koz94]. Such axiomatizations might not only be interesting in their own right, but could prove useful in cases where the relations have or can be given a useful operational interpretation.

5.3.4. Data representation optimization

Coercion reduction by rewriting appears to be useful in representation optimization, such as *boxing* analysis [Jør95], for recursively defined types. To be practically useful this may, however, require admitting more powerful transformations, for example the isomorphism $S \times (T + U) \cong (S \times T) + (S \times U)$. Seeking a coinductive axiomatization of Kleene Algebras appears to be a useful theoretical step in this direction.

5.3.5. Extensions to richer type languages and systems

We have studied recursive types and subtyping within a type language of monomorphic types; that is, simple types extended with regular recursive types. It would be interesting to extend this study to richer type disciplines with polymorphism (predicative and impredicative), intersection types and object typing.

Acknowledgments

We would like to thank Martín Abadi, Luca Cardelli, Andrew Gordon, Furio Honsell, Gérard Huet, Jakob Rehof, Simona Ronchi della Rocca, Dave Sands, Mads Tofte and the anonymous referees for helpful discussions, feedback, corrections, and pointers to related or interesting literature. Martín Abadi suggested the notion of a level-stratified interpretation of judgements which is the basis of the soundness proof presented in this paper. (An alternative soundness proof can be found in Brandt [Bra97].) Furthermore, he has provided interesting and helpful pointers to relevant topics and literature. Dave Sands pointed out the coinductive nature of recursive type equality in the early stages of this work and provided valuable help during a number of discussions over a period of two years.
